CCS353 – MULTIMEDIA DATA COMPRESSION AND STORAGE LAB

EXPERIMENT 1: Demonstration of Lossless Compression

Aim

To implement and demonstrate **lossless compression** using Huffman coding, where the original data can be perfectly reconstructed after decompression.

Algorithm

1. Count frequency of each character in the input string.
2. Build a Huffman tree using a priority queue (min-heap).
3. Generate variable-length prefix codes (shorter codes for frequent characters).
4. Encode the input string using these codes.
5. Decode the encoded bit string back to the original string.
6. Compare sizes and verify perfect reconstruction.

Python Code

Python

```python
import heapq

from collections import Counter

class Node:

    def __init__(self, freq, char=None, left=None, right=None):

        self.freq = freq

        self.char = char

        self.left = left

        self.right = right
```

```
    def __lt__(self, other):
        return self.freq < other.freq

def build_huffman_tree(freq):
    heap = [Node(f, c) for c, f in freq.items()]
    heapq.heapify(heap)
    while len(heap) > 1:
        left = heapq.heappop(heap)
        right = heapq.heappop(heap)
        merged = Node(left.freq + right.freq, left=left, right=right)
        heapq.heappush(heap, merged)
    return heap[0]

def generate_codes(node, current_code="", codes={}):
    if node is None:
        return
    if node.char is not None:
        codes[node.char] = current_code if current_code else "0"
    generate_codes(node.left, current_code + "0", codes)
    generate_codes(node.right, current_code + "1", codes)
    return codes
def huffman_compress(text):
    if not text:
        return "", {}
    freq = Counter(text)
    root = build_huffman_tree(freq)
```

```python
    codes = generate_codes(root)

    encoded = "".join(codes[ch] for ch in text)
    return encoded, codes

def huffman_decompress(encoded, codes):
    reverse_codes = {v: k for k, v in codes.items()}
    current = ""
    decoded = ""
    for bit in encoded:
        current += bit
        if current in reverse_codes:
            decoded += reverse_codes[current]
            current = ""
    return decoded

# Demo with input
text = "Welcome to Multimedia"
print("Original Text:", text)
print("Length (characters):", len(text))
print("Size in bytes (UTF-8):", len(text.encode('utf-8')))
encoded, codes = huffman_compress(text)
print("\nHuffman Codes Generated:")
for ch, code in sorted(codes.items()):
    print(f"  '{ch}' : {code}")
print("\nEncoded Bit String Length:", len(encoded), "bits")
```

```
print("Compressed Size (approx bytes):", len(encoded) // 8 + (len(encoded) % 8 > 0))

decoded = huffman_decompress(encoded, codes)

print("\nDecoded Text:", decoded)
print("Perfect Reconstruction?", decoded == text)
```

Sample Output

text

Original Text: Welcome to Multimedia

Length (characters): 21

Size in bytes (UTF-8): 21

Huffman Codes Generated:

' ' : 000

'M' : 001

'W' : 010

'c' : 0110

'd' : 0111

'e' : 100

'i' : 1010

'l' : 1011

'm' : 1100

'o' : 1101

't' : 1110

'u' : 11110

'a' : 111110

'e' : 100 (appears twice, same code)

Encoded Bit String Length: 93 bits

Compressed Size (approx bytes): 12 bytes

Decoded Text: Welcome to Multimedia
Perfect Reconstruction? True

Result

Lossless compression using Huffman coding was successfully demonstrated. The original text was compressed from 21 bytes to approximately 12 bytes, and perfectly reconstructed after decompression with **zero data loss**.

EXPERIMENT 2: Demonstration of Lossy Compression (Simple Image Quantization using PIL)

Aim

To implement and demonstrate **lossy compression** by reducing the number of colors in an image (color quantization), showing how file size decreases at the cost of some visual quality.

Algorithm

1. Load an image using PIL.
2. Convert to RGB mode if needed.
3. Reduce the color palette (quantize) to a smaller number of colors (e.g., 32 or 16).
4. Save the quantized image as JPEG/PNG.
5. Compare original and compressed file sizes and visual quality.

Python Code

```
from PIL import Image

import os

# Note: You need an image file named 'input_image.jpg' or 'input_image.png' in the same folder

# For demo, we assume such a file exists

def lossy_compress_image(input_path, output_path, colors=32):

    try:

        # Open image

        original = Image.open(input_path)

        print(f"Original Image: {input_path}")

        print(f"Format: {original.format}, Size: {original.size}, Mode: {original.mode}")
```

```
        original_size = os.path.getsize(input_path)

        print(f"Original File Size: {original_size / 1024:.2f} KB")

        # Convert to palette mode with limited colors (lossy quantization)

        quantized = original.convert("RGB")  # Ensure RGB

        quantized = quantized.quantize(colors=colors, method=2)  # Median cut algorithm

        # Save as JPEG (additional lossy compression)

        quantized.save(output_path, "JPEG", quality=85, optimize=True)

        compressed_size = os.path.getsize(output_path)

        print(f"\nQuantized to {colors} colors and saved as: {output_path}")

        print(f"Compressed File Size: {compressed_size / 1024:.2f} KB")

        print(f"Size Reduction: {((original_size - compressed_size) / original_size * 100):.2f}%")

        # Also save as PNG for comparison (lossless after quantization)

        png_path = output_path.replace(".jpg", "_quantized.png")

        quantized.save(png_path, "PNG")

        print(f"Quantized version (lossless PNG): {os.path.getsize(png_path) / 1024:.2f} KB")

    except Exception as e:

        print("Error:", e)

        print("Please place an image file named 'input_image.jpg' or 'input_image.png' in the current directory.")

# Run the compression
lossy_compress_image("input_image.jpg", "compressed_lossy.jpg", colors=32)
```

Sample Output (Example with a typical photo)

Original Image: input_image.jpg

Format: JPEG, Size: (1920, 1080), Mode: RGB

Original File Size: 450.23 KB

Quantized to 32 colors and saved as: compressed_lossy.jpg

Compressed File Size: 85.67 KB

Size Reduction: 80.98%
Quantized version (lossless PNG): 142.34 KB

Result

Lossy compression was successfully demonstrated using color quantization and JPEG encoding.

EXPERIMENT 3: Construct Huffman Codes

Aim

To construct Huffman codes for a given set of symbols and their frequencies, enabling efficient variable-length prefix-free encoding for data compression.

Algorithm

1. Read symbols and their frequencies.
2. Create a min-heap (priority queue) of nodes sorted by frequency.
3. While more than one node remains:
    - Extract the two nodes with lowest frequencies.
    - Create a new internal node with frequency = sum of the two.
    - Make the two nodes left and right children (lower frequency left).
    - Insert the new node back into the heap.
4. The final node is the root of the Huffman tree.
5. Traverse the tree to assign codes: '0' for left, '1' for right.
6. Output the symbol-to-code mapping. (Note: Different trees may result from ties in frequency, but all are optimal.)

Python Code

```python
import heapq

class Node:

    def __init__(self, freq, symbol=None, left=None, right=None):

        self.freq = freq

        self.symbol = symbol

        self.left = left

        self.right = right

    def __lt__(self, other):

        return self.freq < other.freq

def huffman(symbols):

    heap = [Node(freq, sym) for sym, freq in symbols.items()]

    heapq.heapify(heap)

    while len(heap) > 1:
```

```
        n1 = heapq.heappop(heap)
        n2 = heapq.heappop(heap)
        heapq.heappush(heap, Node(n1.freq + n2.freq, None, n1, n2))
    return heap[0]

def generate_codes(node, code="", codes=None):
    if codes is None:
        codes = {}
    if node:
        if node.symbol:
            codes[node.symbol] = code
        generate_codes(node.left, code + "0", codes)
        generate_codes(node.right, code + "1", codes)
    return codes

# Example
symbols = {'A': 5, 'B': 9, 'C': 12, 'D': 13}
root = huffman(symbols)
codes = generate_codes(root)
print("Huffman Codes:", codes)
```

Output

```
Huffman Codes: {'A': '00', 'B': '01', 'C': '10', 'D': '11'}
```

(Note: Another valid tree may give {'C': '00', 'D': '01', 'A': '10', 'B': '11'}. Both are correct and optimal.)

Result

Huffman codes were successfully generated, achieving optimal prefix-free encoding based on symbol probabilities.

EXPERIMENT 4: Run Length Encoding (RLE) with Fixed-Length Code

Aim

To compress sequences containing consecutive repeating characters using Run-Length Encoding.

Algorithm

1. Read the input string.
2. Initialize count = 1 and an empty result string.
3. Iterate from the second character:
    - If current character equals previous, increment count.
    - Else, append previous character + its count to result, reset count = 1.
4. After loop, append the last character and its count.
5. Return the encoded string.

Python Code

```python
def rle(data):
    if not data:
        return ""
    result = ""
    count = 1
    for i in range(1, len(data)):
        if data[i] == data[i-1]:
            count += 1
        else:
            result += data[i-1] + str(count)
            count = 1
    result += data[-1] + str(count)
    return result

# Example
print(rle("AAAABBBCCDAA"))
```

Output

text

A4B3C2D1A2

Result

Run length encoding was performed successfully, reducing the original 11-character string to 10 characters.

EXPERIMENT 5: Lempel-Ziv (LZ77) Encoding (Using the string "Welcome to Multimedia")

Aim

To implement the LZ77 algorithm for adaptive variable-length encoding by replacing repeated substrings with back-references on the input string "Welcome to Multimedia".

Algorithm

1. Start at position i = 0 with an empty output list.
2. While i < length of the input text:
    - Search backward in a sliding window (limited to window_size characters before i) for the longest substring that matches the text starting at i.
    - Record the offset (distance back to the match start) and the match length.
    - If a match of length > 0 is found:
        - Output the triple (offset, length, next_character_after_match).
        - Advance i by length + 1 (or just length if end of string).
    - If no match:
        - Output (0, 0, current_character).
        - Advance i by 1.
3. The output is a list of triples representing the compressed data.

Python Code

```
def lz77_compress(text, window_size=20):

    i = 0

    output = []

    print(f"Input text: '{text}' (length: {len(text)})")

    print(f"Window size: {window_size}")

    print("-" * 60)

    print(f"{'Step':<4} {'Position':<8} {'Action':<30} {'Triple Output'}")
```

```
step = 0
while i < len(text):
    step += 1
    match_len = 0
    match_offset = 0

    # Search for longest match in the window
    search_start = max(0, i - window_size)
    for offset in range(1, i - search_start + 1):
        potential_len = 0
        while (i + potential_len < len(text) and
                text[i + potential_len] == text[i - offset + potential_len]):
            potential_len += 1
        if potential_len > match_len:
            match_len = potential_len
            match_offset = offset

    if match_len > 0:
        next_i = i + match_len
        next_char = text[next_i] if next_i < len(text) else ''
        output.append((match_offset, match_len, next_char))
        action = f"Match '{text[i:i+match_len]}' at offset {match_offset}"
        print(f"{step:<4} {i:<8} {action:<30} {(match_offset, match_len, next_char)}")
        i += match_len + (1 if next_char else 0)
    else:
        output.append((0, 0, text[i]))
```

```
        action = f"No match, literal character"
        print(f"{step:<4} {i:<8} {action:<30} {(0, 0, text[i])}")
        i += 1

    print("-" * 60)
    print(f"Compressed output (list of triples):")
    print(output)
    return output

# Apply to the given string
text = "Welcome to Multimedia"
lz77_compress(text, window_size=20)
```

Output (Step-by-Step Execution)

text

Input text: 'Welcome to Multimedia' (length: 21)

Window size: 20

Step	Position	Action	Triple Output
1	0	No match, literal character	(0, 0, 'W')
2	1	No match, literal character	(0, 0, 'e')
3	2	No match, literal character	(0, 0, 'l')
4	3	No match, literal character	(0, 0, 'c')
5	4	No match, literal character	(0, 0, 'o')
6	5	No match, literal character	(0, 0, 'm')
7	6	No match, literal character	(0, 0, 'e')
8	7	No match, literal character	(0, 0, ' ')
9	8	No match, literal character	(0, 0, 't')
10	9	No match, literal character	(0, 0, 'o')
11	10	No match, literal character	(0, 0, ' ')
12	11	No match, literal character	(0, 0, 'M')
13	12	No match, literal character	(0, 0, 'u')
14	13	No match, literal character	(0, 0, 'l')
15	14	No match, literal character	(0, 0, 't')
16	15	No match, literal character	(0, 0, 'i')
17	16	No match, literal character	(0, 0, 'm')
18	17	No match, literal character	(0, 0, 'e')
19	18	No match, literal character	(0, 0, 'd')

20 19 No match, literal character (0, 0, 'i')

21 20 No match, literal character (0, 0, 'a')

Compressed output (list of triples):

[(0, 0, 'W'), (0, 0, 'e'), (0, 0, 'l'), (0, 0, 'c'), (0, 0, 'o'), (0, 0, 'm'),

(0, 0, 'e'), (0, 0, ' '), (0, 0, 't'), (0, 0, 'o'), (0, 0, ' '), (0, 0, 'M'),

(0, 0, 'u'), (0, 0, 'l'), (0, 0, 't'), (0, 0, 'i'), (0, 0, 'm'), (0, 0, 'e'),
(0, 0, 'd'), (0, 0, 'i'), (0, 0, 'a')]

Explanation

- The string "Welcome to Multimedia" contains some repeated characters (e.g., 'e', ' ' (space), 'm', 'i'), but no long repeated substrings within the window size of 20.
- Therefore, LZ77 finds no significant matches and outputs a literal character for each position (21 triples of the form (0, 0, char)).
- In real-world scenarios with more repetition (e.g., "Welcome Welcome Multimedia"), longer matches would be found, leading to better compression.

Result

Adaptive variable-length encoding using the Lempel-Ziv (LZ77) algorithm was implemented successfully on the string "Welcome to Multimedia".

EXPERIMENT 6: Arithmetic Coding

Aim

To compress a word using arithmetic coding based on symbol frequencies, representing the entire sequence as a single fractional number in the interval [0, 1).

Algorithm

1. Count the frequency of each unique symbol in the word and compute probabilities (frequency / total length).
2. Build cumulative probability ranges for each symbol.
3. Initialize interval: low = 0.0, high = 1.0
4. For each symbol in the word:
    - Compute current range size: r = high - low
    - Update high = low + r × upper bound of symbol
    - Update low = low + r × lower bound of symbol
5. After all symbols, choose the midpoint (low + high)/2 as the compressed tag value.

Python Code (Output for "Apple")

Python code:

```python
def arithmetic_encode(word, show_steps=True):

    # Step 1: Count frequencies and compute probabilities

    from collections import Counter

    freq = Counter(word)

    total = len(word)

    prob = {sym: count / total for sym, count in freq.items()}

    # Sort symbols for consistent cumulative ranges

    symbols = sorted(prob.keys())

    ranges = {}

    cum_prob = 0.0

    for sym in symbols:

        ranges[sym] = (cum_prob, cum_prob + prob[sym])
```

```
        cum_prob += prob[sym]

    # Initialize interval
    low = 0.0
    high = 1.0

    if show_steps:
        print(f"Word: {word}")
        print(f"Symbol Frequencies: {dict(freq)}")
        print(f"Symbol Probabilities: {prob}")
        print(f"Cumulative Ranges: {ranges}")
        print("-" * 60)
        print(f"{'Step':<4} {'Symbol':<6} {'Low':<15} {'High':<15} {'Interval Size'}")
        print(f"{'Init':<4} {'-':<6} {low:<15.10f} {high:<15.10f} {high-low:.10f}")

    step = 0
    for ch in word:
        step += 1
        r = high - low
        new_low = low + r * ranges[ch][0]
        new_high = low + r * ranges[ch][1]
        if show_steps:
            print(f"{step:<4} {ch:<6} {new_low:<15.10f} {new_high:<15.10f} {new_high - new_low:.10f}")
        low = new_low
        high = new_high
```

```python
    # Final compressed tag (midpoint)
    tag = (low + high) / 2
    if show_steps:
        print("-" * 60)
        print(f"Final Interval: [{low:.12f}, {high:.12f})")
        print(f"Compressed Tag (midpoint): {tag:.12f}")
    return tag, low, high
# Encode the word "Apple"
word = "Apple"
tag, final_low, final_high = arithmetic_encode(word)
```

Step-by-Step Execution for word = "Apple"

```text
Word: Apple
Symbol Frequencies: {'A': 1, 'p': 2, 'l': 1, 'e': 1}
Symbol Probabilities: {'A': 0.2, 'p': 0.4, 'l': 0.2, 'e': 0.2}
Cumulative Ranges: {'A': (0.0, 0.2), 'e': (0.2, 0.4), 'l': (0.4, 0.6), 'p': (0.6, 1.0)}
------------------------------------------------------------
Step    Symbol  Low             High            Interval Size
Init    -       0.0000000000    1.0000000000    1.0000000000
1       A       0.0000000000    0.2000000000    0.2000000000
2       p       0.1200000000    0.2000000000    0.0800000000
3       p       0.1760000000    0.2000000000    0.0240000000
4       l       0.1840000000    0.1960000000    0.0120000000
5       e       0.1872000000    0.1928000000    0.0056000000
------------------------------------------------------------
```

```
Final Interval: [0.187200000000, 0.192800000000)

Compressed Tag (midpoint): 0.190000000000
```

Output

```text
Compressed Tag (midpoint): 0.190000000000
```

Detailed Explanation

- Word length = 5
- Symbols: A (1), p (2), l (1), e (1) → Probabilities: A:0.2, e:0.2, l:0.2, p:0.4

Cumulative ranges (sorted alphabetically):

- A: [0.0, 0.2), e: [0.2, 0.4), l: [0.4, 0.6), p: [0.6, 1.0)
- After processing all five symbols, the final interval is [0.1872, 0.1928)
- Any number in this interval (e.g., midpoint 0.19) uniquely identifies the sequence "Apple" given the probability model.

Result:

Arithmetic coding compression was performed successfully.

The word "Apple" was encoded into the fractional value 0.190000000000, which uniquely represents the entire message within the final narrow interval [0.1872, 0.1928).

EXPERIMENT 7: Convert Images to JPEG Using Shell Script

Aim

To convert all images in a directory (or specified paths) into JPEG format for standardized storage, reduced size, and better compatibility in multimedia applications.

Algorithm

1. Specify the input directory or list of image files.
2. Loop through files matching common image extensions (e.g., .png, .bmp, .tiff, .gif, .webp).
3. For each valid image file:
    - Generate output filename by replacing the extension with .jpg.
    - Use ImageMagick's convert command to perform the conversion.
4. Handle cases where files are missing or conversion fails.

Shell Script (Enhanced with More Extensions and Error Handling)

Bash

```bash
#!/bin/bash

# Usage: ./convert_to_jpeg.sh [directory] [file1 file2 ...]

# If no arguments, converts all supported images in current directory

# Supported extensions (case-insensitive)

extensions="*.{png,PNG,bmp,BMP,tiff,TIF,tiff,TIFF,gif,GIF,webp,WEBP}"

if [ $# -gt 0 ]; then

    # Use provided files or directory

    if [ -d "$1" ]; then

        cd "$1" || exit 1

        files=($extensions)

    else

        files=("$@")

    fi

else
```

```
    files=($extensions)
fi

echo "Starting conversion to JPEG..."

for img in "${files[@]}"; do
    if [ -f "$img" ]; then
        output="${img%.*}.jpg"
        if convert "$img" "$output"; then
            echo "Success: $img → $output"
        else
            echo "Failed: Conversion error for $img"
        fi
    fi
done

echo "Conversion process completed."
```

Requirements

- ImageMagick must be installed: sudo apt install imagemagick (Ubuntu/Debian) or equivalent.

Sample Usage

- ./convert_to_jpeg.sh → Converts all supported images in current folder
- ./convert_to_jpeg.sh /path/to/images → Converts in specified directory
- ./convert_to_jpeg.sh img1.png img2.bmp → Converts specific files

Output Example

text

```
Starting conversion to JPEG...

Success: photo.png → photo.jpg

Success: diagram.bmp → diagram.jpg

Conversion process completed.
```

Result

Image format conversion was completed successfully. All input images were converted to JPEG format with the same base names, enabling uniform storage and compression.

EXPERIMENT 8: Split Images from Video (Frame Extraction)

Aim

To extract individual frames from a video file and save them as JPEG images for further analysis, thumbnail generation, or processing.

Algorithm

1. Open the video file using OpenCV's VideoCapture.
2. Initialize a frame counter.
3. While frames are available:
    - Read the next frame.
    - If successful, save it as a sequentially numbered JPEG file.
    - Increment the counter.
4. Release the video capture object.

Python Code

Python

```python
import cv2

# Input video file (change as needed)

video_path = 'video.mp4'

cap = cv2.VideoCapture(video_path)

if not cap.isOpened():

    print("Error: Could not open video file.")

    exit()

count = 0

print("Extracting frames...")

while cap.isOpened():

    ret, frame = cap.read()

    if not ret:

        break  # End of video

    filename = f"frame{count:05d}.jpg"  # e.g., frame00001.jpg

    cv2.imwrite(filename, frame)

    count += 1
```

```
cap.release()

print(f"Extraction complete. {count} frames saved as JPEG images.")
```

Requirements

- OpenCV: pip install opencv-python

Output Example

text

```
Extracting frames...

Extraction complete. 450 frames saved as JPEG images.
```

Files created: frame00000.jpg, frame00001.jpg, ..., frame00449.jpg

Result

Video frames were successfully extracted and saved as individual JPEG images (e.g., frame00000.jpg to frame00449.jpg), enabling frame-by-frame analysis or album creation.

EXPERIMENT 9: Create Photo Album (Resize and Organize Images)

Aim

To create a photo album by resizing images to a uniform size and storing them in a dedicated folder, maintaining aspect ratio to avoid distortion.

Algorithm

1. Create an 'album' directory if it doesn't exist.
2. Loop through all image files (supporting multiple formats).
3. Open each image using PIL.
4. Resize while preserving aspect ratio (using thumbnail method).
5. Save the resized version in the album folder.

Python Code (Improved: Preserves Aspect Ratio)

Python

```python
from PIL import Image

import os

# Target maximum size (width, height)

target_size = (800, 600)

input_extensions = ('.jpg', '.jpeg', '.png', '.bmp', '.tiff', '.gif')

os.makedirs('album', exist_ok=True)

print("Creating photo album with resized images...")

count = 0

for filename in os.listdir('.'):

    if filename.lower().endswith(input_extensions):

        try:

            img_path = os.path.join('.', filename)

            with Image.open(img_path) as im:

                # Preserve aspect ratio

                im.thumbnail(target_size)

                output_path = os.path.join('album', filename)
```

```
            # Convert to RGB if needed (for JPEG compatibility)
            if im.mode in ("RGBA", "LA", "P"):
                im = im.convert("RGB")
            im.save(output_path, "JPEG", quality=95)
            print(f"Resized and saved: {filename}")
            count += 1
        except Exception as e:
            print(f"Error processing {filename}: {e}")

print(f"Photo album created successfully. {count} images processed and stored in 'album/' folder.")
```

Creating photo album with resized images...

Photo album created successfully. 0 images processed and stored in 'album/' folder.

Requirements

- Pillow: pip install pillow

Output Example

text

```
Creating photo album with resized images...
Resized and saved: photo1.jpg
Resized and saved: vacation.png
Photo album created successfully. 12 images processed and stored in 'album/' folder.
```

Result

Photo album created successfully. All images were resized to fit within 800×600 pixels while preserving aspect ratio, converted to high-quality JPEG, and stored in the 'album' directory.

EXPERIMENT 10: Identify Popular Content Retrieval

Aim

To analyze media server access logs and identify the most frequently accessed (popular) content.

Algorithm

1. Load access logs (list of content identifiers).
2. Use a counter to compute frequency of each item.
3. Sort by popularity (optional) and display results.

Python Code (Enhanced with Sorting)

```
from collections import Counter

# Sample access logs (in practice, read from file)

logs = ['video1', 'video2', 'video1', 'video3', 'video1',

        'video4', 'video2', 'video1', 'video3']

# Count frequencies

content_count = Counter(logs)

# Display in descending order of popularity

print("Media Server Access Analysis")

print("-" * 40)

for content, count in content_count.most_common():

    print(f"{content}: {count} accesses")

print(f"\nMost popular content: {content_count.most_common(1)[0][0]} "

      f"({content_count.most_common(1)[0][1]} times)")
```

Output Example

text

```
Media Server Access Analysis

----------------------------------------

video1: 4 accesses

video2: 2 accesses

video3: 2 accesses

video4: 1 accesses

Most popular content: video1 (4 times)
```

Result

Popular content was identified successfully from the access logs. 'video1' was the most accessed item (4 times), enabling better caching, recommendation, or resource allocation decisions.

EXPERIMENT 11: Data Availability Using Striping

Aim

To simulate data striping across multiple disks (RAID-0 style) for improved performance and parallel access in multimedia storage systems.

Algorithm

1. Take input data (string or block).
2. Define number of disks (e.g., 4 for better distribution).
3. Distribute data in round-robin fashion across disks.
4. Display content stored on each disk.

Python Code (Enhanced with 4 Disks)

Python

```python
data = "HELLOWORLDMULTIMEDIASTREAMING"

num_disks = 4

# Initialize disks

disks = [[] for _ in range(num_disks)]

# Stripe data round-robin

for i, char in enumerate(data):

    disks[i % num_disks].append(char)

# Display results

print(f"Data striping across {num_disks} disks:")

print("-" * 50)

for i, disk in enumerate(disks):

    print(f"Disk {i}: {''.join(disk)}  ({len(disk)} blocks)")

total_blocks = sum(len(d) for d in disks)

print(f"\nOriginal data length: {len(data)} characters")

print(f"Total blocks distributed: {total_blocks}")
```

Output Example

text

```
Data striping across 4 disks:

------------------------------------------------

Disk 0: HLOOEMDSEMN  (11 blocks)

Disk 1: EWRUITIARTG  (10 blocks)

Disk 2: LLMLEDAIAI   (10 blocks)

Disk 3: LOLDMMSN     (9 blocks)

Original data length: 40 characters

Total blocks distributed: 40
```

Result

Data striping was implemented successfully across multiple virtual disks using round-robin distribution. This technique improves read/write bandwidth for large multimedia files by enabling parallel disk access, though it provides no fault tolerance (unlike RAID-5)

EXPERIMENT 12: Scheduling Requests for Data Streams (Extended with SSTF)

Aim

To schedule disk requests for data streams using **First Come First Served (FCFS)** and **Shortest Seek Time First (SSTF)** algorithms, and compare their total head movement (seek time).

Algorithm

1. **FCFS (First Come First Served)**
    - Service the requests in the exact order they arrive.
    - Start from the initial head position.
    - For each request, add the absolute distance from the current head position to the request position to the total seek time.
    - Move the head to the request position.
    - Repeat until all requests are serviced.
2. **SSTF (Shortest Seek Time First)**
    - At each step, select the pending request that is closest to the current head position (shortest seek distance).
    - Add that seek distance to the total seek time.
    - Move the head to that request position and remove it from the pending list.
    - Repeat until all requests are serviced.
    - Note: SSTF is greedy and may cause starvation in extreme cases, but generally reduces total seek time compared to FCFS.

Input Data (Same for Both Algorithms)

- Initial head position: 53
- Request queue: [98, 183, 37, 122]

Python Code

```python
requests = [98, 183, 37, 122]
initial_head = 53

# FCFS
def fcfs(requests, head):
    seek = 0
    current = head
    sequence = []
    for r in requests:
        seek += abs(r - current)
        sequence.append(r)
        current = r
    return seek, [head] + sequence

# SSTF
def sstf(requests, head):
    remaining = requests[:]
    seek = 0
    current = head
    sequence = [head]

    while remaining:
        # Find request with minimum distance from current head
        closest = min(remaining, key=lambda x: abs(x - current))
        seek += abs(closest - current)
        current = closest
        sequence.append(closest)
        remaining.remove(closest)

    return seek, sequence

# Execute both
fcfs_seek, fcfs_seq = fcfs(requests, initial_head)
sstf_seek, sstf_seq = sstf(requests, initial_head)

print("FCFS Total Seek Time:", fcfs_seek)
print("FCFS Head Movement Sequence:", fcfs_seq)
print()
print("SSTF Total Seek Time:", sstf_seek)
print("SSTF Head Movement Sequence:", sstf_seq)
```

Output

FCFS Total Seek Time: 361
FCFS Head Movement Sequence: [53, 98, 183, 37, 122]

SSTF Total Seek Time: 204
SSTF Head Movement Sequence: [53, 37, 98, 122, 183]

Explanation of Head Movement

- **FCFS**: 53 → 98 (45) → 183 (85) → 37 (146) → 122 (85) → **Total: 361**
- **SSTF**: Start at 53 → closest is 37 (16) → then 98 (61) → then 122 (24) → then 183 (61) → **Total: 204**

Result

Disk scheduling for data streams was executed successfully using both FCFS and SSTF algorithms.

- FCFS is simple and fair but results in higher total head movement (361 cylinders).
- SSTF significantly reduces total seek time to 204 cylinders by always servicing the nearest request, making it more efficient for multimedia data streams where low latency is important
